

Experimental Protocol: Technomouse Resonance Capture

Date: July 13, 2026

I. Core Objective

To achieve sustained energy transduction from the 7D toroidal bulk into 4D spacetime by aligning physical material resonance with the mathematically identified topological peak.

II. Material & Fabrication Requirements

- Geometry:** The resonator must utilize a logarithmic spiral (Nautilus) geometry to mimic natural fluid flow and minimize topological drag.
- Metasurface Coating:** Surface must be etched with a topological pattern manifesting $SU(3)$ color symmetry for bulk-to-brane potential gating.
- Conductivity:** High-dielectric, non-linear photonic glass required for quantum discharge transduction.

III. Calibration Protocol

- System Initialization:** Boot the 7D HTFT system.
- Resonance Scan:** Execute the automated frequency sweep (400–450 Hz) to map local topological potential.
- Optimization:** Use the objective function to lock the system onto the exact peak frequency (f_{opt}).
- Load Balancing:** Activate the autonomous agent to match energy extraction to real-time external demand.

IV. Safety & Conservation

The device operates as a topological diode, ensuring unidirectional energy flow. Momentum conservation is maintained through the transfer of topological torque from the 7D manifold to the resonator.
